## Analysis of APT-GET

BENOÎT BAUFAYS

Université Catholique de Louvain

### Abstract

*This paper will deal with analysing the managing software apt-get which are deployed on several linux distributions*

### I. INTRODUCTION

Apt-get is a software developed for linux OS to centralize the management of your software. Apt-get install packages containing precompiled code, configuration files, and meta-information about the package. Because it is not very useful to manage manually all your packages, apt-get was created. With him, you can update your system and your packages but you can also install or remove packages. The utility of apt-get is the management of the dependencies and, with one program, you can maintain your system up to date.

### II. APT-GET

Apt-get have several commands, depending on what you want to do.

- update : with this command, apt-get search, on remote servers, the last version for all packages. It get also the entire list of packages you can install via apt-get;
- upgrade or dist-upgrade : with this command, apt-get downloads packages installed on your system which are to be updated. The difference between the command "upgrade" and "dist-upgrade" is

that, with the first, apt-get doesn't install new packages. For example, some packages must require new dependencies. If you update with the first command, apt-get doesn't install new dependencies and, of course, doesn't update the package. In other hand, with the second command, apt-get install all dependencies and update all packages;

- install : with this command, you can install new package. Apt-get search for dependencies and install the package and the required packages;
- remove : with this command, apt-get remove the package mentioned. It can also remove packages which are not still required on your system. For example, if a package is only installed because it is a dependency for another package and you remove this package, it is not required to have the dependency's package on your system.

Apt-get have several other commands but the main has been presented below. To analyse how apt-get works and deal with network, we will use the same order presented in the list below. But, before, we discuss about the IPv6 and apt-get.

### III. APT-GET AND IPV6

To know where it must searching informations about packages, apt-get have one file "/etc/apt/sources.list" which contains addresses of servers. According to several bloggers, apt-get have some troubles with IPv6 because some servers have no Ipv6 address or the ISP doesn't support it.

To verify this information, we have used dig to send a DNS request to archive.ubuntu.com, the main server for every sources.

```
;; QUESTION SECTION:
;archive.ubuntu.com.      IN      AAAA

;; ANSWER SECTION:
archive.ubuntu.com.      425     IN      AAAA    2001:67c:1360:8c01::19
archive.ubuntu.com.      425     IN      AAAA    2001:67c:1360:8c01::1a
archive.ubuntu.com.      425     IN      AAAA    2001:67c:1360:8c01::22
archive.ubuntu.com.      425     IN      AAAA    2001:67c:1360:8c01::23
archive.ubuntu.com.      425     IN      AAAA    2001:67c:1360:8c01::15
archive.ubuntu.com.      425     IN      AAAA    2001:67c:1360:8c01::18
```

As we can see, archive.ubuntu.com have several IPv6 address, the problem do not come from that. When we go deeper in the code of apt-get, we see that some fonctionnalités are still using IPv4 libraries.

### IV. APT-GET ANALYSIS

#### I. Update

##### I.1 DNS Request

With this command, apt-get read first the file containing all server's name. With this information, it sends DNS request to know IP address of each server.

```
DNS 79 Standard query A security.ubuntu.com
DNS 79 Standard query A security.ubuntu.com
DNS 73 Standard query A dl.google.com
DNS 77 Standard query A ppa.launchpad.net
DNS 77 Standard query A extras.ubuntu.com
DNS 79 Standard query A toolbelt.heroku.com
DNS 81 Standard query A be.archive.ubuntu.com
DNS 223 Standard query response A 91.189.92.201 A 91.189.92.202 A 91.189.91.13
DNS 79 Standard query A security.ubuntu.com
DNS 223 Standard query response A 91.189.92.190 A 91.189.92.200 A 91.189.92.201
TCP 231 Destination unreachable (port unreachable)
DNS 268 Standard query response CNAME dl.l.google.com A 173.194.112.6 A 173.194
DNS 73 Standard query A dl.google.com
DNS 93 Standard query response A 91.189.95.83
```

As we can see, Apt-get send first all his DNS requests before contacting servers. We see also that dl.google.com, an entry that we have

added manually to access to packages from Google (GoogleTalk, ...) is, in reality, reachable via dl.l.google.com. Finally, we can see that apt-get send twice the DNS request about dl.google.com. It's not because it doesn't receive the response but because we have added twice this entry in the config file.

To test the DNS system, we have put manually a arbitrary IP address for the second DNS server. This test is visible in the schema below with the "Destination unreachable" message. After that, apt-get doesn't reuse this IP address to send DNS query.

When we analysing packets receive by apt-get, we see that the time life of the information is 3 minutes 30. Also, we see that it receive more than one IP address for every server name. With this solution, apt-get doesn't want to resend a DNS query if a IP address down. With multiple IP addresses, it can also use multi threading and request informations on multiple servers.

#### I.2 Getting information

With the IP address, apt-get can now getting informations about packages. These informations are getting in two step.

```
HTTP 574 GET /skunk/pepper-flash/ubuntu/dists/precise/release.gpg HTTP/1.1 GET /webupd8team/ubuntu/dists/precise
DNS 79 Standard query A toolbelt.heroku.com
DNS 268 Standard query response CNAME dl.l.google.com A 173.194.112.6 A 173.194.112.7 A 173.194.112.8 A 173.194.112.9
TCP 74 33485 > http [SYN] Seq=0 Win=14600 Len=0 MSS=1460 SACK_PERM=1 TSval=4294907300 TSecr=0 WS=128
TCP 74 http > 37522 [SYN, ACK] Seq=0 Ack=1 Win=14480 Len=0 MSS=1452 SACK_PERM=1 TSval=529080805 TSecr=4294907294 WS=22
TCP 66 37522 > http [ACK] Seq=1 Ack=1 Win=14720 Len=0 TSval=4294907301 TSecr=529080805
HTTP 300 GET /ubuntu/dists/precise/release.gpg HTTP/1.1
DNS 225 Standard query response A 91.189.92.201 A 91.189.92.202 A 91.189.91.13 A 91.189.91.14 A 91.189.91.15 A 91.189.9
TCP 74 58406 > http [SYN] Seq=0 Win=14600 Len=0 MSS=1460 SACK_PERM=1 TSval=4294907302 TSecr=0 WS=128
TCP 74 http > 58404 [SYN, ACK] Seq=0 Ack=1 Win=14480 Len=0 MSS=1452 SACK_PERM=1 TSval=515324992 TSecr=4294907298 WS=22
TCP 66 58404 > http [ACK] Seq=1 Ack=1 Win=14720 Len=0 TSval=4294907304 TSecr=515324992
HTTP 311 GET /ubuntu/dists/precise-security/Release.gpg HTTP/1.1
TCP 66 http > 30954 [ACK] Seq=509 Ack=576 Win=15744 Len=0 TSval=4294907309 TSecr=307927781
HTTP 331 GET /skunk/pepper-flash/ubuntu/dists/precise/release HTTP/1.1
TCP 553 [TCP Previous segment lost] HTTP/1.1 304 Not Modified
TCP 70 [TCP Dup ACK 364] 30554 > http [ACK] Seq=509 Ack=1 Win=14720 Len=0 TSval=4294907300 TSecr=307927781 RST=289 R
TCP 304 [TCP Out-of-order] HTTP/1.1 304 Not Modified
TCP 66 39954 > http [ACK] Seq=509 Ack=576 Win=15744 Len=0 TSval=4294907309 TSecr=307927781
HTTP 331 GET /skunk/pepper-flash/ubuntu/dists/precise/release HTTP/1.1
```

First, as we can see in the schema above, apt-get get some files with HTTP 1.1. Before, it do a three handshake (SYN, SYN-ACK, ACK) to open the connection. For example, after having open a connection with the server, apt-get download "http://extras.ubuntu.com/ubuntu/dists/precise/Release". Because it's a file readable, we have downloaded it to see how apt-get works.

```

```

For each subfiles, containing informations about packages, it receive the MD5 sum or the SHA1 sum (not present in the schema), the size of the file you will download and, finally, the path to download the file. In fact, it's not a file, it's a archive. With this solution, ubuntu compress informations.

With the schema above, we can also see that apt-get still send and receive DNS query while we have noticed, in the previous subsection that apt-get send all his queries before getting informations about packages. It's true for main addresses but, for addresses you have added manually, apt-get begin to download informations about packages before it have finished

```

136 main/binary-amd64/Release
11858 main/binary-amd64/Packages.gz
35415 main/binary-amd64/Packages
10788 main/binary-amd64/Packages.bz2
29551 main/binary-armel/Packages
8776 main/binary-armel/Packages.bz2
136 main/binary-armel/Release
9606 main/binary-armel/Packages.gz
9606 main/binary-armhf/Packages.gz
136 main/binary-armhf/Release
8776 main/binary-armhf/Packages.bz2
29551 main/binary-armhf/Packages
35407 main/binary-1386/Packages
135 main/binary-1386/Release
10788 main/binary-1386/Packages.bz2
11855 main/binary-1386/Packages.gz
8776 main/binary-powerpc/Packages.bz2
9606 main/binary-powerpc/Packages.gz
29551 main/binary-powerpc/Packages
138 main/binary-powerpc/Release

```

DNS queries for personnalized addresses.

We see also how apt-get retrieve from lost packets (dark line in the schema). Because apt-get use TCP, it receive first a packet that indicate the lost segment. With this information, apt-get send back a duplication acknowledgement. In this example, we have added a delay for some packets and we can see that, after the duplication acknowledgement, apt-get receive the lost packet and TCP say "TCP out of order". it means that this packet arrive not in the correct order. it's logical because with put a delay for one packet.

After having downloaded the main file, apt-get download archive listed in the main file. If you download also the archive, you can see that it contains one file, listing all packages and informations about each : checksum, name, description, last version, dependencies, ... With this file, apt-get can updated his local informations and test if you have the last version. If not,
